

EPM Case Analysis

The trouble with diagnosis and treatment of neuromuscular diseases is there are many that look alike, it's complicated. Veterinarians are trained to figure out the subtleties of the presenting signs, conduct a neurological exam, record a thorough clinical history, implement diagnostic procedures and diagnostic tests that help them select a treatment. Another exam will be needed to see if the treatment worked. The veterinarian needs to know how the treatment is expected to work, what will change, and how long the treatment will be effective. Follow up labs are needed to make sure there are no unintended consequences of the treatment. We emphasize the importance of clinical exams and testing for the diseases we work with. That is how we conducted our research and make we make our results available in our consulting program.
